

Zero Waste World

Although a fully Zero Waste World is not currently reachable (however it was just a couple years ago), we can still try to reduce any possible waste and improve our behaviour towards the environment.

Human behaviour is the main cause of problems in this topic and until we change the way we behave we cannot change the fact.

Many people consider plastic products the biggest villain of the environment, however the „greenest“ country in terms of Zero Waste World is South Korea, which also has one of the biggest amount of plastic waste thrown out, how is that possible?

Not all plastic is bad, we just have to make it recyclable enough. This regards also many metals such as aluminium which can be recycled almost forever, the can you throw away one day can be sold as new the next day to someone else.

The next problem is not just the production nevertheless our demand, if we reduce our demand for many unnecessary products (buying an invulnerable refillable bottle instead of a plastic one every day)

Personally, I would try to publicly point out most of the things that the human behaviour towards the environment can cause

Taking into consideration the stated points above, I therefore conclude that the human behaviour and demand is the biggest problem in this topic and until we decide to take responsibility for our actions, we cannot reach even a fraction of the Zero Waste World.
